

## **BIOLOGICAL PRODUCTS DATABASE - BY SOURCE & TRADE NAME**

**About this database and how to use it** - This Biological Product Database is a tool for growers that will assist with navigating the array of 'biological' products currently available to their farming business. We have compiled the information in response to questions from growers about available products. (Webinar on biopesticides available <u>here</u>.)

**Definition** - 'Biological' products (also called 'biologicals') are defined as those that are derived from living organisms (plants, animals, microorganisms, fungi). The term encompasses a diverse range of products, and this is a fast-growing segment of agricultural inputs (definition from www.croplife.org).

This database includes a column that indicates whether products have APVMA registration (Australian Pesticides and Veterinary Medicines Authority). Registered products are known as 'Biological Crop Protection' products. If a product is used for crop protection (i.e., used as a biopesticide) is must be registered for use in the crop and situation it is applied in. Contact the APVMA or Hort Innovation for more information. For products not registered with the APVMA, potential effects suggested by manufacturers are NOT efficacy claims and data on potential for phytotoxicity or residues do not exist.

**How was the database developed?** We have gathered information primarily from the manufacturers, via their websites and/or their representatives. We have attempted to strip away any confusion by laying out the bare bones of each product. We will include references to independent research in the database as the project progresses and we receive information from independent research.

The database is a work in progress - The database is a work in progress and is not comprehensive. We have not carried out reviews of science-based literature for each product. If a column or cell is blank, it does not meant that there is no information, just that we have not found it yet (this is particularly the case for independent trial information). The database will be updated and published regularly as information becomes available.

**Is anything missing?** If you know of any products or trial information we have failed to include, or details that are inaccurate or incomplete, please either complete the spreadsheet at the bottom of this webpage (www.soilwealth.com.au/resources/global-scan-and-reviews/biological-products-database/) and/or get in touch - rm@rmcg.com.au.

**DISCLAIMER:** VERY IMPORTANT - This document does not include or offer advice of any kind. It is a collection of publicly available information. Very few products have been registered by the APVMA, a process that entails rigorous independent testing of efficacy, residues, phytotoxicity and potential effects on flora, fauna and people. We do not endorse any products and the database is not an exhaustive list. To the best of our knowledge the information is correct at the time of publishing. Always refer to product label for Directions for Use.

These explanations of 'Source' and 'Product Type' have been developed to provide clarity and aid with interpretation of the Biological Products Database. Some products do not fit neatly within these, where this is the case, the aim has been to provide the best fit for the product details available.

## **BIOLOGICAL PRODUCTS DATABASE - EXPLANATIONS - SOURCE**

microbial	Microbial products are products derived from various small, simple organisms. Microbial products may contain the organisms themselves and/or the metabolites they produce. Microbial products generally contain or are derived from four different subcategories:
	• Bacteria - may prevent plant diseases by outcompeting plant pathogens in the rhizosphere, producing anti-fungal compounds, and by promoting plant and root growth. Examples of beneficial bacteria include Bacillus subtilis, Bacillus pumilus, Pseudomonas spp., and Streptomyces spp.
	• Protozoa - while most protozoa feed on bacteria and decaying organic matter, a wide range of protozoan species are insect parasites. For example, the protozoan <i>Nosema locustae</i> is known to be a natural biocontrol agent of many grasshopper species.
	• Viruses - can be very specific to particular insects or arthropods. For example, certain viruses can kill only one or a few species of Lepidoptera larvae (caterpillars), making them good candidates for management of crop pests with minimal off-target effects. The granulovirus of the codling moth ( <i>Cydia pomonella</i> ), or CpGV, is a good example of a commercially successful viral insecticide.
	• Yeasts - may work through competition with pathogens, e.g. for nutrients. For example, Candida oleophila Strain O, has been developed as an effective biocontrol for post-harvest fruit rots. It is applied to apples and pears after harvest — but before storage — to control particular fungal pathogens causing post-harvest decay such as grey mould (Botrytis cinerea) and blue mould (Penicillium expansum). Candida oleophila Strain O works primarily through competition for nutrients and pre-colonisation of plant wound sites.
plant extract	Water- or solvent-based plant extracts or essential oils (EOs) can contain valuable natural products, many of which can be used safely in pest and disease control due to their ability to degrade quickly. An important consideration is that EOs and plant extracts are biologically unstable as they are easily destroyed by environmental pH, oxygen, light, and moderate temperatures. EOs exhibit poor aqueous solubility and high volatility in general. Many extracts or EO biopesticides are often used without deeply understanding their mode of action. Water- or solvent-based extracts and EOs can improve plant resistance to biotic and abiotic stressors, and can be involved in metabolic processes that control plant tolerance to these stressors.
amino acids	Amino acid products are manufactured either by hydrolysis or enzymatic treatment of animal or plant protein feedstock. Amino acids are readily absorbed, transported, and utilised as a source of nitrogen and carbon for plants. This saves the energy expended by the plant to reduce organic matter, synthetic nitrates and ammonia into amino acids. Some amino acids are efficient metal ion chelators which can help with metal ion nutrient uptake and help protect plants from toxic levels of metal ions.
	Amino acids also function as biostimulants for plants, playing important roles in enhancing plant productivity, especially under abiotic and biotic stress conditions. Refer to <a href="https://www.growerssecret.com/amino-acids-as-biostimulants">https://www.growerssecret.com/amino-acids-as-biostimulants</a>

## **BIOLOGICAL PRODUCTS DATABASE - EXPLANATIONS - SOURCE (CONTINUED)**

seaweed extract	An extract produced from seaweed. It is usually a concentrated organic product (usually liquid, but can be soluble granules) that can be diluted and applied to seedlings and transplants as well as larger plants – see comments below for the specific functions of humic and fulvic acids.
	Nutrient content: Seaweed is a rich source of many essential plant nutrients such as nitrogen, phosphorus, potassium, and trace elements like iodine, zinc, and iron which can improve soil fertility.
	Microbial growth: Seaweed can act as a source of carbon and energy for microorganisms in the soil, stimulating their growth and activity.
	Root growth: Some studies suggest that seaweed extracts can have a positive impact on root growth and root health, which can improve overall plant growth and vigour.
	Disease suppression: The compounds present in seaweed can have an antimicrobial effect, inhibiting the growth of certain pathogens and helping to suppress plant diseases.
	Alginates: Seaweed contains alginates, a complex carbohydrate that can form gels in soil, which can improve soil structure and water-holding capacity, making it more conducive to healthy microbial growth.
	Hormones: Seaweed contains growth hormones like cytokinins and auxins that can promote root growth, cell division and elongation, which can help plants to better cope with environmental stress.
fish extract	Fish extract (also emulsion, or fish fertiliser) for plants, is a fast-acting, organic liquid product made from the by-products of the fishing and aquaculture industries. It is rich in nitrogen, phosphorus, and potassium, plus trace elements such as calcium, magnesium, sulphur, chlorine, and sodium.
seaweed/fish mix	A mix of seaweed and fish extracts described above.

## **BIOLOGICAL PRODUCTS DATABASE - EXPLANATIONS - SOURCE (CONTINUED)**

## humic/fulvic acid

When plants and animals are decomposed by bacteria, humic substances are released and are found naturally in soils. Humic substances are composed of: relatively small fulvic acids that dissolve in both acid and alkaline environments, larger humic acids that are soluble under alkaline conditions, and very large humins that are insoluble. Humic acids can be 100 000 times larger than fulvic acids. Humic acids used in soil amendments are often extracted from brown coal.

#### **Humic acid**

Humic acids can aid with nutrient cycling, microbial growth and disease suppression through the following mechanisms:

Nutrient cycling: Humic acids can help to make nutrients such as nitrogen and phosphorus more available to plants by chelating or complexing them, making them more accessible to plant roots.

Microbial growth: Humic acids can act as a source of carbon and energy for microorganisms in the soil, stimulating their growth and activity.

Disease suppression: Humic acids can also have an antimicrobial effect, inhibiting the growth of certain pathogens and helping to suppress plant diseases.

#### **Fulvic acid**

Fulvic acid may stimulate root growth and affect root function to exude organic acids that can lead to increased nutrient uptake.

Fulvic acid can also help to increase plant nutrient uptake by chelating (binding) minerals and other nutrients. Chelated minerals are easier for the plant to absorb and use.

## **BIOLOGICAL PRODUCTS DATABASE - EXPLANATIONS - PRODUCT TYPES**

Product to control the growth of fungi and fungal spores. They can be made from a variety of chemical compounds including synthetic chemicals, botanicals, and microbial pesticides.
Product to kill or control weeds. They can be made from a variety of chemical compounds, including synthetic chemicals, botanicals, and microbial pesticides. Some herbicides target specific weeds or groups of weed (e.g. grasses), while others have a broader spectrum of activity.
Product to kill or control a population of insects. They can be made from a variety of chemical compounds, including synthetic chemicals, botanicals, and microbial pesticides. Some insecticides target specific insects, while others have a broader spectrum of activity.
Product to kill or control a population of mites. They can be made from a variety of chemical compounds, including synthetic chemicals, botanicals, and microbial pesticides.
A plant pest deterrent is a substance or method used to prevent or discourage the presence of pests. These pests can include insects, mites, nematodes, and other animals that feed on plants or cause damage to the foliage, roots, or fruit of plants. Plant pest deterrents can include a variety of chemical and non-chemical methods, such as:
Biological controls, such as the use of predators or pathogens that feed on or kill pests
Botanical repellents, such as certain essential oils or plant extracts that have been shown to repel certain pests and also
<ul> <li>Physical barriers, such as screens or nets, which can physically prevent pests from reaching the plants.</li> </ul>
A plant disease suppressant is a substance or method that is used to prevent or reduce the incidence or severity of plant diseases. These diseases can be caused by a variety of pathogens, such as bacteria, fungi, viruses, and nematodes. Disease suppressants can include a variety of chemical and non-chemical methods, such as:
1. Biological controls: The use of beneficial microorganisms such as bacteria or fungi that can outcompete or inhibit the growth of pathogens in the soil or on the plant surface.
2. Botanical extracts and essential oils: Some plant extracts and essential oils have been found to have antimicrobial properties, which can help to suppress the growth of pathogens.
Products should be supported via:
1. Crop rotation: rotating crops can help to reduce the build-up of pathogens in the soil, which can help to reduce the incidence of diseases.
2. Cultural controls: Sanitation practices, such as removing and destroying infected plant debris, can help to reduce the incidence of diseases.
3. Nutrient management: Proper nutrition can help plants to better cope with disease stress and improve overall plant health.
4. Environmental control: Manipulating the environment by controlling temperature, humidity, light intensity can help plants to better cope with pathogens.

## **BIOLOGICAL PRODUCTS DATABASE - EXPLANATIONS - PRODUCT TYPES (CONTINUED)**

stress	There are several ways to increase stress resistance in plants; the following may be used in <b>products</b> :
resistance	1. Microorganisms: Some microorganisms can promote plant growth and stress tolerance by improving nutrient uptake, protecting against pathogens, and producing plant growth-promoting compounds.
	2. Hormonal treatments: Some phytohormones such as cytokinins and gibberellins have been shown to increase stress tolerance in plants by promoting cell division and elongation.
	However, sole reliance on products will not be successful. Other methods that should be used at the same time are:
	<ol> <li>Variety selection (breeding): Selecting and breeding plants that are naturally more tolerant to stress conditions such as drought, heat, cold, and disease.</li> <li>Proper nutrition: Providing plants with adequate and balanced nutrition can help them to better cope with stress.</li> </ol>
	3. Water management: Proper irrigation and drainage can help plants to better tolerate drought stress and prevent effects of waterlogging.
	4. Mulching: Mulching, e.g. planting into cover crop residues, can help to reduce soil moisture loss, moderate soil temperature and suppress weed growth, which can help plants to better tolerate stress conditions.
	5. Crop rotation: rotating crops can help to reduce the build-up of pests and diseases, as well as improve soil health, which can help plants to better tolerate stress conditions.
	6. Environmental control: Manipulating the environment by controlling temperature, humidity, light intensity can help plants to better tolerate stress conditions.
crop nutrition product	Crop nutrition products can include a variety of chemical and organic compounds that provide plants with macronutrients and/or micronutrients (such as zinc, copper, and iron). These products can be applied to soil or foliage in various forms such as granular, liquid, and foliar sprays.
growth stimulant/ regulator	A plant growth stimulant is a substance or a microorganism that when applied to plants, can improve their growth and development. Plant growth stimulants can be in the form of hormones, enzymes, minerals, or microorganisms that are applied to the soil or the foliage of plants. They can be used to improve crop yields, and/or increase the tolerance of plants to environmental stress. Some examples of plant growth stimulants include auxins, cytokinins, gibberellins (which are produced by plants) or humic acids which naturally occur in soils.
soil biology stimulant	A soil biology stimulant is a substance that is used to enhance the diversity and activity of microorganisms in the soil, which can improve soil health and plant growth. Soil biology stimulants can include a variety of microorganisms such as bacteria, fungi, and protozoa, as well as organic compounds such as humic acids (see 'Source' definitions above) and seaweed extracts. The microorganisms help to break down organic matter, improve nutrient cycling, and promote root growth, leading to healthier and more productive plants. Soil biology stimulants can be applied through soil drench, foliar spray or seed coating.
wetting agent	A chemical added to reduce the surface tension of a liquid and allow it to spread more easily and evenly over plant surfaces (reduces beading). Also known as a surfactant.
